A new wave of chemistry: how geochemistry can predict tsunamis (pp. 23–25)

- 1 Mean titre volume of EDTA = $\frac{19.14 + 19.17 + 19.13}{3} = 19.15 \text{ cm}^3 = 0.01915 \text{ dm}^3$
 0.01915 dm³ of 0.01 mol dm⁻³ EDTA contains 0.0001915 mol of EDTA
 1 mole of EDTA reacts with 1 mole of Ca²⁺, therefore 25.00 cm³ of the test solution contains 0.0001915 mol of Ca²⁺
 25.00 cm³ = 0.02500 dm³
 Concentration of Ca²⁺ in the sample = $\frac{0.0001915 \text{ mol}}{0.02500 \text{ dm}^3} = 0.00766 \text{ mol dm}^{-3}$

CFCs, HFCs and the ozone layer (pp. 26–31)

- 1 a i CFC-13
 ii HCFC-225 (HCFC-225ca)
 b i CHCl₂F
 ii C₂HCl₂F₃ (actually CHCl₂CF₃)
- 2 a i ¹²C³⁷ClF₃⁺ (or ¹⁴C³⁵ClF₃⁺)
 ii ¹²C³⁵ClF₂⁺
 iii ¹²CF₃⁺
 iv ¹²CF₂⁺
 b The C–Cl bond energy is smaller than the C–F bond energy, which means that the C–Cl bond preferentially breaks. This leads to the CF₃⁺ ion being more abundant, rather than CClF₂⁺.
- 3 All the fluorine atoms in Cl₃C.CF₃ are in the same electronic environment, whereas those in ClF₂C.CCl₂F experience two different environments (being attached to different carbons with differing numbers of chlorines and fluorines). Therefore Cl₃C.CF₃ will give a simpler spectrum (than ClF₂C.CCl₂F), with just one signal.
